Could you add assert_equal tests to each function as I have done for the index function?

Absolutely. I added `assert_equal` tests for all 164 functions in your football-scoring program.

164 functions covered

Download the updated Python file

What I added

1. Page-return tests: Each function is called with a sample `State`, and `assert_equal` checks that it returns a `Page`.
2. State-change tests: Functions that modify scores, field goal statistics, conversions, punts, or turnovers also have assertions checking those changes.
3. Custom-team tests: Both custom team submission functions are tested with sample names and colors.

One important distinction

I kept your original program intact and added the tests before `start_server()`.

The tests are primarily smoke tests and state-change tests rather than complete comparisons of every returned `Page` against an expected `Page`, like your original `index` test.

I would recommend eventually adding those more detailed comparisons for your most important pages, particularly the scorekeeping and final statistics pages.

Why are all of the field goal related functions failing?

I found the problem: my tests expected the wrong number of successful field goals.

In `_test_state()`, each team's `field_goal_made` value starts at `1`:

```
return State(..., 10, 10, 2, 1, 2, 1, ...)
```

When a successful field goal function runs, it adds one:

```
state.away_field_goal_made += 1
```

So the correct result is `2`, not `3`. The tests for the field-goal page functions are different: those increment the attempt count from `2` to `3`, so their expected value of `3` is correct.

I corrected all six successful-field-goal tests (regulation, second half, and overtime for both teams).

Download the corrected Python file

The actual field-goal functions were not the problem; the expected values in my tests were.
